AGENDA FOR RESEARCH IN DRY REGIONS: 
SOCIO-ECOLOGICAL PERSPECTIVE

By
Anil K. Gupta

W P No. 537
November 1984

The main objective of the working paper series of the IIMA is to help faculty members to test out their research findings at the pre-publication stage.

INDIAN INSTITUTE OF MANAGEMENT

INDIA
AGENDA FOR RESEARCH IN DRY REGIONS: SOCIO-ECOLOGICAL PERSPECTIVE*

There has been expressed, in recent past, lot of concern towards the problem of improving level of living of majority of small producers in regions with poorer ecological endowment and higher environmental risks. Existence of low population density, generally dispersed settlements, very high degree of heterogeneity in natural resources endowment (soil fertility and topography, rainfall pattern within small localities, intensity of various factors causing ecological imbalance etc) together with historical accumulation of deficits in the household budgets of most of the poorer people required a very different analytical approach for studying the problems of dry regions than the one generally adopted. Research framework suitable for uniformly endowed irrigated regions would obviously prove totally inadequate for dry regions (Krishnaswamy and Patel 1973, Vyae et al 1976, Gupta 1981). Yet, the macro developmental policies as well as design of delivery system (including the decentralised agencies like DRDA) hardly demonstrated any specific adaptation to the complexity of dry regions.

*This note includes, general researchable issues based on my own work as well as by others in CMA and outside. Detailed assessment of my own work (1981-84) is presented in the note entitled, "Future Research concerns in Dry farming Regions: a Self-critical review" 1984 and review of CMA studies other than mine on Dry farming during 1973-1983 are included in the note, "Analytical Review of Selected CMA studies in dry Regions: 1973-1984."
The problem was compounded when research resource allocation for dry regions also remained highly restricted due to both supply and demand factors (Joche 1983, Gupta 1981). The continued neglect of dry region problem has already been manifested in several respects such as high rural-urban migration from these regions; stagnancy in production of pulses besides some oilseeds and millets; severe constraint of draught power which further restricted adoption of many of the new time-bound technological packages; recent spurt in violence around grazing lands and inequitous access to private fallows as well as village commons; increasing regional imbalances and of course massive expenditures on relief necessitated due to frequent droughts or in some parts even occasional snap floods. The technological, administrative and organizational, socio-economic and cultural aspects of dry region problems required an inter-disciplinary approach which socio-ecological perspective recently developed at the CMA helped in pursuing comprehensively.

We have reviewed some of the important studies done by CMA in last decade in this regard separately. The important implications flowing from these studies have been very briefly drawn upon in the list of issues mentioned below. Since it is a preliminary draft no attempt has been made to list the problems in the order of priority. It is also possible that some of the relevant concerns might have been ignored or underplayed due to author's biases or just inadvertently. It is expected that discussion on this note will generate both, a priority for CMA's concerns in this regard and also a perspective
for focussing attention of other fellow researchers interested in the subject.

It may be added that historical bias in national research policy towards irrigated regions has generated a peculiar dilemma for social science research. Most of the senior researchers with very few exceptions, even when began with the enquiries in dry regions, got lured into the extremely attractive research opportunities available in better endowed regions. Thus when national attention started being focussed on dry region problem in recent past, it is learned that not many institution and individuals appeared interested or available for pursuing these problems. Those who indeed showed interest tended many times to apply perspectives and skills developed in dealing with problems of irrigated regions. Further the internationally sponsored research also has contributed in someways, towards complicating the above scenario. Therefore when we look at the management concerns in dry farming research we may find above backdrop probably useful. It has

1Dr. Jodha(1983) in a recent paper underscored few more dimension of this problem such as professional unattractiveness due to inability of dry regions to ensure, "use of standardized methods, stability of results and possibility of quick and assured rewards through experimentation under usually high input conditions". He also refers to the use of dry farming research stations as centres of punishment pastings just the way it was done in bureaucracy. Prof. Vyas (1976) mentioned how people on punishment, probation or promotion were posted to these regions with often very transient interest/stakes in solution of long and short term problems.

2Management is a science of anticipation. It is used here in a wider context in which conceptual problems of generating relevant futuristic research issues and pragmatic approach of concurrent problem solving are very delicately balanced. The focus is on organization, institutions and systems (public or private) which intervene indirectly through markets or directly through programmes/projects affecting farmer level decision making.
implications for not only generating right questions but also ensuring 
that there were people identified who would pursue these with the right 
perspective and persuasion. Networking amongst the already involved 
scientists would become a logical concomitant of this need and CMA is 
in an unique position to perform this role.

Conceptual framework

Several CMA studies in past, notably the ones pursued by Profs. 
Krishnaswamy, Srivastava, Vyas and rural development group including 
Profs. Ranjit Gupta, BM Desai, TK Moulid, etc. have pointed out the 
need for conceptualising the problems of dry regions differently from 
the other better endowed regions. Recently a socio-ecological perspec-
tive on household economy in semi-arid regions has been developed 
synthesizing lot of earlier work by this author as well as others. In 
figure one given in Appendix-one, the key elements of this framework 
are listed.

Essentially it implies that mix of economic enterprises (crop, 
livestock, craft, labour etc.) in any given region was defined by the 
ecological conditions in a historical context. The scale at which differ-
ent classes of producers operated these enterprises depended upon the 
historical reserve of surpluses or deficits, access to credit, labour 
and product market (which are crucially interrelated), risk bearing 
capacity etc. The technological choices in various sectors, spaces and 
of different classes could be appraised in the given Mean variance

3 Detailed discussion on this perspective is provided in the study by 
Anil K Gupta on "small Farmer Household Economy in Semi-arid Regions, 
1984, forthcoming."
matrix which was socio-ecologically defined. This generated in a cumulative manner different perception of risk inherent in dry region economy at the level of various households. The diversification of enterprises, technological level, access to institutions, perception of risk vis-à-vis actual risk, access to public, communal risk adjustment devices etc generated stable or unstable cashflows. These in turn led to accrual of surpluses at some holdings and deficits at another. The stakes in environmental protection were a critical function of whether a household had a surplus, subsistence or deficit budget. This ultimately in a dynamic end crop specie mix found at the level of different classes of farmers toge-
way modified the mix of enterprises. Thus the typical livestock with other dependence upon migration (seasonal or permanent), non-farm craft activities etc. reported by various researchers could be analysed in above framework.

Some of the structural features of dry region ecology like less population density, dispersed settlement system, high degree of labour mobility etc. were mentioned in the beginning. Some other associated features could be added such as, fragmentation of holdings, higher incidence of salinity and alkalinity hazards, predominant role of livestock (generally bigger farmers specializing in grazers with poorer farmers and labourers in browsers), very poor administrative and institutional infrastructure, considerable reliance on relief through externally injected resources (see Jodha 1983, Vyas and Khanna, 1982) and high level of income disparities accentuated through exploitive role of big farmer-
trader-lender in particularly years of crop failure or livestock epi-
demics.
We may suggest two cautions at this stage:

One) We should guard against the possibility of falling into the trap of 'ecological determinism'.

Two) Following from above, policy framework (whether for prices, rates of interest, insurance, subsidies, institutional design etc.) for dry regions could not be explored in isolation of the framework for other regions.

The implications of above would become clearer when we discuss the research options given below:

Research Options:

Institutional/Organizational

1. Design or Delivery System

a) Can sedentary organizations designed to serve sedentary populations serve mobile population? How to organize delivery systems which did not pass on the problem of gaining access on to the poor who should either organize, protest or demand the services which these organizations are in fact set up to supply?

b) The cost of delivery in low population-density regions was inherently high. Similar financial and budgetary allocations here per capita or per unit of area would intensify regional imbalances. How to design fiscal policies which avoided such an outcome?

c) Many times while replicating programmes across different ecological regions, the uniform administrative set up was followed for instance, in T & V System. If a TV was expected to cover same number of households or village in high & low population

---

4Also see, Anil Gupta, 1984 Role of Public enterprises in backward region, IIMA, W.P. No. 511.
density villages, it was inevitable that services should suffer in the backward region. How to design bureaucratic structures for various programmes including DRDA which took different structural constraints into account?

d) In risky regions, the delivery system was expected to perform more efficiently because, one) the markets were very weak, two) the uncertain rainfall necessitated a high degree of preparedness and resourcefulness on the part of the farmer. How to design monitoring and control systems which ensured that reverse was not the case.

There were several other issues like, existence of large number of vacancies, absence of any incentives for postings in such areas, lack of basic amenities, predominance of female headed households (when male migrated away seasonally and bureaucracy proved singularly ineffective in dealing with women clientele), uniform population and costing norms in terms of per capita or number of people per unit of facility (e.g. a bank branch was expected to serve 17000 people all over the country regardless of population density), similar budgetary system despite known and predictable instances of delay, uniform location norms (guided often by growth centre theory which had proved highly inadequate for developing economies) etc. As the review of DRDA studies shows, large number of institutional inadequacies have been noted in revenue (or so called regulatory wing) administration having implications for development. While employment oriented programme as well as drought relief works continued to remain with revenue administration, the myth of developmental and regulatory dichotomies in administration continued to influence training and research efforts in development. There is
urgent need to look into systematically the links which already exist, and also the ones which need to be forged between various wings of administration and organization in dry regions. Highly diversified households in such regions necessitate highly diversified program delivery.

8. Technology

a) There is a need to document the traditional selection criteria for varietal selection in crops as well as livestock so as to integrate these organically with the breeding objectives for future. e.g. in a labour surplus economy, synchronous varieties severely constrain the option of subsistence households to manage sowing or harvest within a limited period of time.

b) There is a need for social science contribution at the Ex-Ante stage of setting up technological priorities. The scope of such interaction will depend upon the ability of management scientists to demonstrate the feasibility of such contribution of identifying precise characteristics of the niches for new technologies as well as the constraints at various levels of farmers to be resolved by these technologies.

c) Against 'package' approach, recent attempts amongst dry farming scientists to develop 'tiers of technology' deserve better and urgent attention of management scientist so as to improve technological diffusion process.

d) Risk has been known to be an important factor inhibiting experimentation with high mean-high variance technology. Instead of/or together with direct relief, there is a need to launch action-research
projects on credit-linked insurance* so as to trigger technological transition in a big way. The real trade off is between sustained expenditure of huge amount in adhoc manner and massive investments now so as to reduce future needs for relief.

e) In case of livestock, the draft power constraint is becoming extremely severe. In some region number of bullocks has gone down in absolute terms in last two decades. This has direct implication for timely sowing, land preparation, interculture, bullock or camel drawn implements etc. Likewise livestock breeding policies for dry region also need to be looked into.

Another problem which is likely to assume serious proportions in near future is the problem of violence around grazing lands. The extraordinary spurt in dry fodder prices during 1979-80 drought caused lot of distress amongst poor leading to disposal of livestock in large number of cases. Policy for divising a public storage and distribution system for fodder in dry regions needs an urgent attention.

c) Cottage Industries

In case of cottage industries which have flourished historically most importantly in dry region, there were large number of issues which needed attention. Some of the problems were, a) the value addition locally as against the outside (e.g. wool, leather, sisal etc.) b) skill and technological upgradation besides ofcourse marketing and credit support to artisans c) there were certain crafts which were adversely

*Also see, Anil K Gupta 1983, Credit Arrangement for drought Prone region: Policy prescription and Planners reactions, IIM-WP 478.
affected by public policies of revenue extraction (e.g. recent decision
to auction palm trees for toddy extraction rights in a particular
state affected those who made brooms with its leaves), lot of employ-
ment potential existed in other cases like sisal processing but
viable organizational alternatives remained to be developed, the export
 corporations for those goods often procured the goods through interme-
diaries in the absence of effective KVIC system, import policy (for
instance for wollen rage, yarn etc.) affected the prices of products
of artisans many times adversely, etc.

There was a need to study the organic link that existed between
crop-craft-labour and livestock as mentioned earlier so that mutually
reinforcing policy set emerged for dry regions.

IROP in dry regions

There was an urgent need to explore alternative model of IROP
for dry regions which could effectively deal with many of the points
made already. The weak marketing structure of the produce of poor was an
important lacuna as was the problem of supply of raw material (e.g.
even in a tribal district, the bamboo had to be bought from outside
for basket making whereas local bamboo was marketed/contracted out).
The norms regarding subsidy, procurament, insurance (insurance compa-
nies did not renew the policy in case of sheep and goat)\(^5\), provision
of second loan, failed enterprise subsidy (knowing the large scale fail-
ure was quite likely in such regions) followup and rehabilitation etc.
needed careful attention. Even the structure of DRDA and the population
coverage norms as proposed in the background papers for VIIth Five
year plan needed reconsideration.

\(^5\) See the study on ecological adaptation of credit delivery system in
Jharkhand by Prof. Anil K Gupta and Prof. Manu Shroff, 1984, forthcoming
(part of ongoing rural development Action Research Project of
CMR-PSG coordinated by Prof. Ranjit Gupta on Creation of demand groups.)
(E) **Credit Policy**

Large number of studies have been done at CMA and elsewhere on the problem of credit. There are several schools of thought ranging from the one which calls for higher rate of interest and major role to informal lenders (Deasi 1976) to those who argue for a totally different approach to credit for dry regions (Gupta 1983) emphasizing subsidy for making organization viable and at the same time promoting portfolio approach to credit disbursement for multi-enterprise poor households.

Key issues needing attention are:

a) How to organize delivery system for disbursing large number of small loans needed frequently and repayable in cash, labour or kind?*

b) How to devise viable policy for developing different repayment schedules in different ecological regions and for various classes of farmers for the same enterprise due to different level of consumption deficits.

c) How to ensure the branch expansion policy of banks particularly RRB is not biased against dry region? How to develop different viability norms for RRB and its branches in dry regions? How to devise control policies for subsidising cost of RRB operations in dry regions?

d) There is a need to devise monitoring systems which ensure a match between Bank portfolio and enterprise mix of poor in different regions? Today eventhough District Credit Plans were

*Anil K Gupta 1983 Impoverishment in Drought prone regions, SDC/NABARD/IFMA RBI minor. Also see a case written on the subject by Prof. BM Deasi (1976) - based on Gharampur project.*
prepared block and purposewise, they were monitored sectorwise and that too at district level.

c) How to improve the coordination system between banks and district administration? To whatever extent the banks still remain the only autonomous organizations at district level, the problem of authority vis-à-vis influence of collector remained an endemic problem in most of the districts despite posting of RBI lead officers.

d) The credit allocation for certain enterprises in which majority of poor were engaged like sheep, craft, etc was even less than fraction of a percent in many of the drought prone districts.

e) Innovative systems for credit delivery to nomadic or semi-nomadic populations also needed to be developed.

f) The problems of overdues had assumed serious proportions. However no particular relationship was observed between probability and extent of crop failure in a particular mixed region with overdues in a recent study. The regions with least risk infact had more overdues at district taluka and village level (in taluks of a particular district) in Gujarat. Also the financing done during 1969-71 in the early phase of nationalization (when banks lacked enough experience) needed a very different treatment from the rest. Likewise scarcity-induced-genuine overdues deserved to be dealt with differently from the other more deliberate type of overdues.
There hardly existed any policy for rephasing and rehabilitation of loans without Gazette notification in commercial banks.

In fact, despite the fact that formal credit intervention began with Doongan rints triggered by extraordinary spurt in informal rates of interest and exploitation by money lenders after drought, no specific policy bias for credit in dry regions has still now been created in the country. At the same time policies for making loan costlier for bigger and irrigated farmers also needed to be vigorously pursued and explored.

(f) *Restorations of Ecological Balance*

Eventhough one of the major objective for ORAP was restoration of ecological balance, the progress in this regard has been extremely tardy. Recent studies have shown the importance of silvicultural system (Prof. Tirtha Gupta 1983) and also provided evidence that poor were better conservator of resources (Gupta 1984). There was a need to systematically review the existing policies of central and states in this regard to build proper framework for landuse in dry regions.

- Problem of shorter time frame in which poor had to manage survival and longer time frame in which rich managed surplus extraction posed the key dilemma in dry regions. The fragile social balance amongst losers and gainers (the beneficiaries of public investment in irrigation and electrification) in dry regions hinges to a great extent on the way public interventions will be made or not in future.

Management discipline has a vital role to play by contributing towards the design of organization, institutions and access modes enabling poor to influence and ultimately control the resource flow. Role of state becomes singularly important in dry region which often fail to attract market forces.
