ABSTRACT

In the present paper, an attempt is made to construct Input-Output Tables for Rajasthan compatible and consistent with the national I-O tables for the year 1984-85 which formed the basis for the national 7th Five Year Plan. Input-Output coefficient matrix and input transaction matrix for Rajasthan are presented for 50×50 commodity sectors at the current (1984-85) prices. Both the survey based and non-survey based methods of estimating the I-O tables are used. A detailed comparison of the estimates reveals that non-survey based method used in the paper performs satisfactorily to capture the overall regional differences from the national technology. If, however, the purpose is to capture sector-activity-specific differences in the regional technology, the survey-based method should be preferred over the non-survey based method although it involves much greater time and effort.

INPUT-OUTPUT TABLES FOR RAJASTHAN :
METHODOLOGY AND ESTIMATES

BAKUL H. DHOLAKIA

1. Need for Regional Tables

Inter-Industry table, popularly known as input-output (I/O) table, is an accounting device to represent the flows of transactions taking place in an economy over a given period of time which is generally taken to be a year. It captures the sectoral inter-dependence, basic structure and broad technology in the economy. Since development planning in the economy aims at achieving different goals by carefully avoiding bottlenecks and imbalances in the system, the detailed description of the economy provided in the inter-industry table assumes special importance in the planning models. After the Third Five Year Plan, the macro planning models used in India have been based on an input-output table for the whole economy. While such aggregative planning models based on I/O tables ensure internal consistency at the macro level for the specific sectoral targets, they fail to capture the dimension of space. Recent studies on regional disparities have clearly

shown that not only the levels of technology and production structure differ substantially but their rates of change over time also vary considerably across the regions in India (R.H. Dholakia, 1985). In order to make the plan targets more realistic, it is, therefore, necessary to incorporate the spatial dimension explicitly into the planning model.

One approach to tackle this problem is to decentralize the planning process by adopting the multi-level planning framework so as to capture the local circumstances and information more effectively. This would require preparation of state plans in the framework of the national plan. The requirement of the internal consistency of the state plans can be met only when the sectoral interdependence and sectoral links existing in the state are clearly spelt out. In other words, an inter-industry table at the state level should be used as the basis for the state plan just as the national inter-industry table is used as the basis for national plan. The state I/O table is expected to capture the basic differences between the state economy and the national economy in terms of the production structure and technology. The method of decentralized planning can thus result in a direct incorporation of the spatial dimension into the overall planning model.

The other approach to deal with the spatial dimension in the national planning is to directly attack the problem by replacing regional I/O tables for the national I/O matrix. In other words, the planning model itself can be modified by decentralizing the I/O table rather than the plan itself. The specific requirement of such an approach is that (i) I/O table for each of the regions in the nation must be prepared; (ii) the reference year for all regional I/O tables must be the same; (iii) the sectoral dimensions of all regional I/O tables should also be the same; and (iv) broad methodology for constructing I/O tables must be the same for all regions.

It is evident that, in both these approaches designed to incorporate the spatial dimension in the national plan model, we require estimation of the regional I/O matrix compatible with the national I/O matrix. Since the I/O tables prove most useful in deriving a consistent estimate of the target of gross output for different sectors on the basis of given levels of final demands, the regional I/O tables are required essentially to get more realistic targets of the gross output in different sectors of the economy.

Another important use of the regional I/O tables is in estimating or forecasting the region specific total demand of critical input industries in future. The regional I/O table

can predict with greater degree of reliability the input demand implications of various alternative developmental strategies under consideration at the regional level. It can also be used to predict the likely effects of any type of supply shocks like drought on the regional economy. Thus, the inter-industry transaction structure in a regional economy is a valuable tool for forecasting the demand for inputs and supply of outputs in the specific regional developmental context. It can also serve as a basis for transport planning since a complete system of regional I/O tables provides the implicit estimates of interregional flows by commodities.

In short, the importance of regional I/O tables compatible with the national I/O table cannot be overstated in the context of realistic planning for economic development in any large sized multi-region national economy like India.

II. Previous Studies for Rajasthan

Efforts in the direction of preparing regional I/O matrices in India were initiated in the 1950's. Subsequently, several individual researchers and institutions have constructed I/O tables for different states during the last two decades. A detailed survey of the availability of regional I-O tables in different states in India has been presented in Prasad and Dalvi (1982). Brief surveys of available studies on regional I-O tables are also presented in Venkatramaiah et. al. (1979) and Saluja (1980).

For Rajasthan, the first attempt for constructing regional I/O matrix was made by Mehta and Bohra (1971) for the reference year 1964-65. Subsequently, Mehta (1983) updated and improved upon the earlier attempt to construct I-O matrix for the year 1970-71. However, the sectoral classification attempted in Mehta's study (1983) was relatively aggregative as it consisted of 10 agricultural sectors, 31 industrial sectors and 8 other sectors accounting for the rest of the economy. The most detailed and relatively comprehensive sectoral classification attempted so far for constructing regional I-O table for Rajasthan has been the one presented in the wider study carried out by Venkataramiah et al. (1979). This study presents a rectangular 60×47 input coefficients matrix for Rajasthan for the year 1965. After 1977, when Mehta's table was first made available, no serious attempt seems to have been made either for updating the existing I-O matrix or for constructing a fresh one for the Rajasthan State. On the other hand, at the national level, the Seventh Plan is based on an I-O matrix of 50×50 for the year 1984-85. It is an updated but abridged version of the I-O table for the year 1973-74 prepared and published by CSO (1981). However, no effort is made to construct compatible I-O matrices at regional level even for the base year 1973-74. The latest year for which the I-O table of Rajasthan is available as of now is 1970-71. It not only involves sectoral mismatch with the latest national I-O table, but it is also very outdated in

terms of the reference year as well as the basic source material. It, therefore, cannot capture adequately the regional differences in technology and production structure. For the same reason, we also cannot use the table prepared by Venkatramaiah et al (1979) as the basic reference table. In view of this, we have to necessarily think in terms of a direct approach to construct the I-O table for Rajasthan compatible and consistent with the latest national I-O table.

III. Basic Approaches for Constructing Regional I-O Tables

There are basically two alternative approaches for estimating the regional I-O matrix, viz., the Survey Method and the Non-Survey Method. In the survey-based method of estimating regional matrix, all the actual input-output transactions are estimated by using whatever information is available on such transactions from the secondary and primary sources for the regional unit. If some gaps in the availability of data are found, they are sought to be bridged by conducting specific primary surveys in the region. On the other hand, the non-survey method of estimating the regional I-O matrix uses the national I-O matrix as the basic reference and modifies it to the necessary extent by using the corresponding estimates of the gross output, value added and other relevant data readily obtainable for the regional unit. In particular, the two approaches differ on the following grounds :

1. While the compatibility and consistency of the regional matrix with the national matrix need to be carefully ensured in the survey method, these are always ensured in the non-survey method.
2. The survey method requires enormous time and effort whereas the non-survey method requires significantly less time and effort.
3. Voluminous amount of data collection and processing is involved in the survey method with the result that its requirement in terms of appropriate software and computer time is substantial. The amount of data collection and processing and hence software requirements are minimal for the non-survey method.
4. As against all the above mentioned disadvantages of the survey method vis-a-vis the non-survey method, the relative merit of the former lies in its ability to capture all of the regional variations in the production technology. While the non-survey method captures some regional variation, it fails to capture all relevant regional variations in production technology including major changes in the input structures of individual industries that may be found at the regional level.

In the present paper, we construct the I-O table for Rajasthan based on both the survey and the non-survey methods. An attempt has also been made to present some comparisons of our regional tables with the national I-O table of 50 x 50 sectors for the year 1984-85. The basic table that we have constructed is the one showing input coefficients of 50 commodity x 50 commodity matrix for Rajasthan. The input transaction table has also been derived by using the corresponding estimates of gross outputs.

IV. Data Sources and Method of Estimation for Survey-Based I-O Matrix

As we have already discussed above, in the survey method we have to take special care to ensure compatibility and consistency of the regional I-O table with the national I-O table. Accordingly, in the present case, we have to ensure compatibility with the national table in the following aspects :

- i) Coverage in terms of the number of sectors and their precise definitions in the I-O table. The Technical Note on Seventh Five Year Plan provides the relevant information about the number and definition of sectors in National I-O matrix. The reference year for the national I-O table is 1984-85 and the table is at current prices. Moreover, it is based on 50-sector

classification of the economy. We have to use the same number and definitions of sectors and the reference year for Rajasthan.

- ii) Concepts used for the regional I-O table should be the same as the ones used for constructing the national I-O table. Particularly, we should ensure that the I-O table should be in terms of commodity x commodity matrix. Further, it should be based on the 'industry technology assumption' which states that the input structure of a secondary product is considered to be similar to that of the industry where it has been produced (see, CSO 1981). Finally the regional I-O table should be in terms of producers' prices for inputs and outputs.
- iii) Apart from the similarity of broad methodology followed in the estimation of input coefficients in different sectors, the adjustment for the following aspects should be on similar lines in the regional I-O table as in the national I-O table : (a) unregistered manufacturing; (b) trade-margins; and (c) indirect taxes.

Keeping these requirements in view to ensure compatibility of the regional I-O table with the national I-O table, we may now outline the details of the methodology adopted in the present paper to construct the survey-based I-O table for Rajasthan for the year 1984-85.

As a first step in the methodology, we divide the regional economy into four broad categories. Since the national I-O table describes the whole economy with 50 sectors/commodities, we classify the same 50 commodities describing the whole economy of Rajasthan into four broad categories based on the following criteria : (i) the level of the sectoral disaggregation given in the national I-O matrix; (ii) the nature of the data availability at the regional level; and (iii) the nature of the activity. The four categories are :

- A. Industry including Electricity (30 sectors)
- B. Agriculture and Animal Husbandry (8 sectors)
- C. Fishing, Forestry and Mining (7 sectors)
- D. Supra-regional Transactors and Services (5 sectors).

We may now discuss the details of the methodology to derive the I-O coefficients for Rajasthan in each of the four above-mentioned categories.

IV-A: Industrial Sector: The industrial sector including electricity covers 30 out of the total of 50 commodities of the economy. It consists of not only the registered manufacturing and electricity sectors but also the unregistered manufacturing sector in the income accounts of the state. Since the basic source material and nature as well as availability of data differ substantially in these two sub-sectors, we distinguish these two segments of the industrial sector and treat

them separately to begin with. Later on we add them to derive the required estimates for the industrial sector.

IV-A (a) : Registered Manufacturing and Electricity

The basic source material in this sub-sector is the detailed tabulation of the factory sector of the Annual Survey of Industries (ASI). The latest year for which these detailed tables of the ASI are available is 1978-79. We have, therefore, made use of this information as the basic source.*¹ Tables 4, 5 and 7 in the ASI detailed tabulation provide very useful information on the inputs and outputs of the registered factories at four digit level of industrial aggregation. These data are both in the physical units and value terms. The data on inputs were classified first into three categories:

- (i) Material inputs
- (ii) Fuel Inputs
- (iii) Other Inputs

Having first identified the four digit level industries for which the data on all these 3 types of inputs are separately available for Rajasthan State, an exhaustive list of the value of material input items by each of the 4-digit level industries was made. This information is available from Tables of the ASI

*1. It may be noted here that the national I-O table for 1984-85 as available in the Technical Note on the 7th Plan, uses the detailed tabulation of ASI for the year 1973-74. However, the tabulation of 1978-79 ASI data was completed subsequently, but it was only in the year 1987 that the corresponding results in the form of relevant detailed tables were available from CSO. We have made use of this most recently available information for constructing the I-O table for Rajasthan.

detailed tabulation. Using the NIC (1970) codes for 8-digit level product/commodity classification, we identified each of the items used as material inputs in each of the ASI 4-digit level industries in the State. Using the definitions of the 50 sectors of the national I-O matrix as given in the Technical Note on 7th Plan and CSO (1981), we then arrived at the aggregation of the 8-digit level inputs item codes into our required sectors for each of 4-digit level ASI industries in the state for the year 1978-79.

Table 4 in the ASI detailed tabulation for the factory sector provides information on the fuel inputs and lubricants used in the production of outputs in different industries at 4-digit level. It provides data on physical units as well as in value terms on 15 categories of fuels and lubricants. The values of these items were collected and aggregated into our required 50 sectors by using the definitions of the sectors for each of the 4 digit level industries.

In the case of other inputs, the information was obtained from Table 7 of the detailed tabulation of ASI, 1978-79 for each of the 4-digit level industry in the state. The broad treatment of different items in Table 7 was similar to the one followed in CSO (1981) which underlies the national I-O matrix for the year 1984-85. Table 7 in ASI detailed tabulation provides information in value terms on the following items which deserve special mention : (i) addition to stock of semi-

finished products, (ii) work done for customers, (iii) sale value of goods sold in the same condition as purchased, (iv) cost of contracts and commission, (v) products reported for sale in last year but used for further manufacture, (vi) miscellaneous charges, (vii) office supplies, (viii) purchase value of goods sold in the same condition as purchased, (ix) cost of repair and maintenance. Whereas the first 3 items relate to output, the remaining 6 items are essentially input items. The difference between (iii) and (viii) is taken as the trade input. Items (iv) and (vi) are allocated to the "other services" sector (Sector No. 50). Item (v) is considered as commodity produced and consumed in the same industry. Item (vii) is broken up equally into two groups of items, viz., paper & stationery and other office equipments. Item (ix) is allocated to "other manufacturing" sector (Sector No. 44).

IV-A (b) : Unregistered Manufacturing

In terms of availability of reasonably detailed information on inputs and outputs, the unregistered manufacturing sector is not at all comparable to the registered manufacturing sector. The data for unregistered manufacturing is collected only through sample surveys which are not very frequently conducted. The latest year for which a detailed sample survey in this sector was conducted through NSSO and for which the results are now available, is 1978-79. It provides information

on aggregate inputs, gross outputs, value added, depreciation, etc. by 2-digit industry groups for major state economies. The results of the central sample are published recently by CSO (1985). Since our required sectoral classification does not match with the 2-digit industrial classification, the first step is to enlarge and match the two classifications. This was accomplished by assuming that within the given 2-digit level industry group, the further disaggregation pattern in the unregistered manufacturing sector is similar to the one in the registered manufacturing sector in the state economy. This method was followed in respect of the aggregates like gross value added and gross output.

Since we do not have any details for the input structure within the unregistered manufacturing, although we have the overall gross value added proportion by industry groups, we have to generate the total input proportions by our required industrial sectors within the unregistered manufacturing in Rajasthan. For the same industry groups, we also have the total input proportions from the ASI tabulations. By adjusting the input-use proportions for the registered manufacturing based on the ASI data to the total input-use proportion in the unregistered manufacturing in each of the required sectors, the required input-use proportions were obtained for the unregistered manufacturing for the year 1978-79.

As we can see from the above discussion, the input-use coefficient matrices for all the sectors covered under the registered as well as unregistered manufacturing pertained to the year 1978-79. We can, therefore, take their weighted average and combine the registered and unregistered manufacturing technologies in the "average" input-use proportions prevalent in the economy. It may be pointed out here that such a procedure of taking weighted average, which is also followed in the national I-O matrix, would necessitate changes in the input-use proportions whenever the relative weightage of the registered and unregistered manufacturing changes in the economy. If we consider any change in the input-use coefficient as revealing the technological change as is often treated in the literature (see for instance, Ramachandra Rao and Narayana 1987), we should treat the changing proportion of registered and unregistered manufacturing as a source for technological change in the economy.

Having obtained the input-use coefficients for the industry sectors for the year 1978-79, the problem was to carry it forward to the year 1984-85. Basically, two different but related phenomena occur in any economy over time in this context : (i) prices of inputs and outputs change at different rates over time; and (ii) the input substitution on account of either changing relative input prices and/or

changing technology takes place. The latter is usually related to the former. It is well-known that relatively cheaper inputs are substituted for relatively costlier inputs. Thus, two opposite effects are likely to operate on the input use coefficients over time. The net impact could be in any direction as far as the input use coefficient in value terms is concerned. We compared the total input use proportions for all the industry sectors covered under registered manufacturing for the year 1978-79 with the ones in the year 1982-83 obtained from the ASI factory sector's summary results for Rajasthan State. The two proportions were found to be remarkably similar in most of the sectors. On the other hand, when we made price adjustments by using the data on price indices by sectors from Finance Ministry (1979; 1983 and 1985) and deflators for state domestic product estimates, the total input use proportions in several sectors were considerably distorted, even to the extent of indicating negative value added proportions in some cases, for both the years 1982-83 and 1984-85. One of the main reasons for this phenomenon may perhaps lie in the fact that such price adjustments at best represent only partial adjustments inasmuch as the corresponding changes in input use proportions in physical terms are not captured by these adjustments. Moreover, it may also be noted that detailed product-wise price information is not readily available at the state level in the required form. In view of

this, it is preferable not to make any price adjustments while deriving regional I-O matrix, especially in the light of available empirical evidence on relative stability of input use coefficients in the short run. Thus, we are in effect assuming that the net impact of relative price changes and inter-input substitution taken together is negligible on the input use coefficients in value terms over the period 1978-79 to 1984-85 in Rajasthan.

In order to generate the transaction matrix, we require to estimate gross output for the year 1984-85 in different industrial sectors covered in our 50×50 sector framework. The latest ASI results for the factory sector are available only in the summary form for Rajasthan state for the year 1982-83. Moreover, these summary results are available for the 3-digit level disaggregation only. On the other hand, the state income data provide the estimates of net value added at current prices in the registered and unregistered manufacturing sectors separately for the year 1984-85. Using the estimate for the rate of depreciation for the registered and unregistered manufacturing sectors from CSO (1987), we generated the gross value added at current prices for these two sectors in 1984-85. Then, by applying the profile of the gross value added for our required industrial sectors from the ASI summary results for the year 1982-83, we obtained the estimates of gross value added in 1984-85 for our different industrial sectors consistent with the

corresponding overall estimate of the gross value added for the entire registered manufacturing sector provided by the official state income statistics. Applying the ratio of gross value added to gross output from the 1982-83 ASI data for Rajasthan by industry groups, the corresponding estimates of gross output by the required sectors were obtained for the registered manufacturing for the year 1984-85.

The 1978-79 data on unregistered manufacturing by the required 30 sectors were similarly processed to obtain the percentage share of gross value added. These percentages were applied to the estimated gross value added for the unregistered manufacturing sector in 1984-85 to get the series of gross value added by the required sectors in 1984-85. The 1978-79 value added proportions for these sectors were used to obtain the corresponding estimates of gross output from gross value added for unregistered manufacturing in 1984-85. The gross outputs in the registered and unregistered manufacturing by the required sectors were then added so as to obtain the corresponding input use transactions matrix for manufacturing in Rajasthan for the year 1984-85 at current prices.

IV-B Agriculture and Animal Husbandry

The main source of data on these sub-sectors is the basic set of worksheets of the state income unit of the Directorate of Economics and Statistics, Government of Rajasthan. From this

source, we obtained the data on gross output by different crops and animal husbandry sub-sectors. However, data on inputs by different items and depreciation were available only for the agriculture and animal husbandry sector as a whole. These data were readily available both at constant and current prices for the year 1984-85. However, in order to allocate the input cost by items to different crops and animal husbandry, we have to use other sources of information. Cost of diesel and electricity were allocated to crops using the statistics on area under irrigation by crops available from the Directorate of Agriculture, Government of Rajasthan. Having generated the transaction columns for the 8 sub-sectors of agriculture in the required 50 x to sector I-O table, these transactions were added to the manufacturing transactions matrix already derived as per the methodology described in the section IV-A above.

¶ In order to adjust these transactions for the trade and transport margins, commodity specific margin rates for Railways, Other Transport and Trade were obtained from the Technical Note on the Seventh Plan. These rates were applied to the transaction table for manufacturing and agricultural sectors. The aggregated margins in each column were then added to their respective sector rows.

IV-C. Fishing, Forestry and Mining :

The main source of data for these sectors is again the state domestic product accounts. From this source, we get the data on net domestic product, depreciation rates and other inputs used by the required sub-sectors at current prices for the year 1984-85. It was, therefore, possible to calculate the total input use proportions and gross value added proportions in these sub-sectors in Rajasthan. The allocation of inputs by commodities in the state was obtained by adjusting the national input use coefficients in each sub-sector at the same rate as the overall input use proportion in the respective sector. The inter-industry transactions were then added to the already obtained transaction matrix for the manufacturing and agriculture.

IV-D. Supra-Regional Transactors and Services :

The main source of data in this sector is also the state income accounts and the CSO. Official estimates of Net State Domestic Product at current prices for the year 1984-85 in these sub-sectors were converted into gross value added by applying sector-specific depreciation rates obtained from the CSO. In the case of the supra-regional transactors like railways, communication, banking and insurance, etc., even the estimates of SDP are received by the state statistical bureau from the CSO. Moreover, in the case of most of

these services, the technology is unlikely to show significant regional variations. National input use coefficients were, therefore, adopted in these sectors and the corresponding transactions were generated.

When these transactions were added to the already derived transaction table, a complete 50 x 50 sector transaction table for Rajasthan State was formed. It was then converted into the input use coefficient form. By post-multiplying this input use coefficient matrix by the Make Matrix obtained from the Technical Note on 7th Plan, the required input-output coefficient matrix for Rajasthan was obtained. The input-output coefficient matrix for Rajasthan for 1984-85, so derived, is presented in Appendix Table 1. The inter-industry transaction table for Rajasthan corresponding to the input-output coefficient matrix for the year 1984-85 at current prices is presented below in Appendix Table 2.

V. Data Sources and Method of Estimation for Non-Survey-Based I-O Matrix

There are several non-survey methods available to regionalize the national inter-industry table. The method that is conventionally used for this purpose is the well-known RAS method (for discussion of RAS method, see Kundu et al., 1978; and Saluja, 1980). Further improvements and refinements in the application of the RAS method is suggested in Braschler et al., (1984). Dalvi and Prasad (1981 and 1982)

have proposed another non-survey method based on the generalized inverse technique. They have also compared the performance of their method based on the Moore-Penrose inverse and the RAS method in the case of the two Indian states. They have found that use of generalized inverse for regionalization of a national I-O matrix can be made for empirical research with a larger degree of confidence as compared to RAS method (see Dalvi and Prasad, 1982). Subsequently, Dholakia and Choudhry (1986) have modified the Dalvi-Prasad (1981) method based on generalized inverse by explicitly introducing the value added constraints. They have demonstrated with the help of the Canadian regional input-output tables for the year 1974 that their method performs far better than the method of Dalvi and Prasad based on the Moore-Penrose generalized inverse. We have, therefore, used the Dholakia-Choudhry method of regionalizing the national I-O matrix for Rajasthan.

Central to the non-survey method based on the generalized inverse technique is the proposition that the national coefficients are weighted averages of the corresponding regional coefficients, the weights being the proportion of regional gross outputs to national gross output in a given industry (j). Symbolically,

$$a_{ij} = \sum_{r=1}^K p_j^r \cdot a_{rj}^r \quad \dots \quad (1)$$

where a_{ij} is the national input use coefficient for the i^{th} commodity in the j^{th} industry, p_j^r is the r^{th} region's share

of j^{th} industry's national gross output and a_{ij}^r is the input use coefficient for the i^{th} commodity in the j^{th} industry for the r^{th} region. In matrix form, (1) may be expressed as :

$$\begin{matrix} A \\ (mxmn) \end{matrix} = \begin{matrix} P \\ (mxmk) \end{matrix} \cdot \begin{matrix} A^R \\ (mkxm) \end{matrix} \dots (2)$$

where n is number of commodities, m is number of industries, and k is the number of regions. All these matrices are defined for the sake of convenience in row diagonal and block diagonal matrix form. (for details, see Dholakia and Choudhry, 1986).

From (2), we obtain :

$$A^R = P^+ \cdot A \dots (3)$$

where P^+ is a generalized inverse of P . Dalvi and Prasad (1981) use the Moore-Penrose generalized inverse of P to get the solution as :

$$a_{ij}^r = p_j^r \cdot a_{ij} / \sum_{r=1}^k (p_j^r)^2 \dots (4)$$

Dholakia and Choudhry (1986) on the other hand, impose the value added constraint and obtain the solution as :

$$a_{ij}^r = a_{ij} \left(\sum_{i=1}^n a_{ij}^r \right) / \left(\sum_{i=1}^n a_{ij} \right) \dots (5)$$

Since the Dholakia-Choudhry method worked far more satisfactorily than the Dalvi-Prasad method, which in turn worked more efficiently than the traditional RAS method, we have used the Dholakia-Choudhry solution to generate the non-survey based Rajasthan matrix from the national input use matrix for the year 1984-85.

The data requirements for this method are relatively less as compared to the other methods. We require the estimates of the value of gross output and total inputs used in each of the 50 sectors for Rajasthan for the given reference year. The most comprehensive source of such data at the state level is generally the state income division of the Directorate of Economics & Statistics of the state government. Although the required data are available at the aggregate sectoral level in the state economy, the same are not always available at the required disaggregated sectoral levels. In such cases, allocation of the aggregates particularly the total inputs used among the corresponding sub-sectors has been made by using appropriate methods.

In order to allocate the total inputs used in a sector, say agriculture, to the sub-sectors covered in our 50×50 classification, we have used the value added proportions obtained from the national table for each of the sub-sectors. Since at the aggregate sector level, we have the regional value added proportion which may be different from the corresponding proportion for the national sector, we adjust the value added proportions in the sub-sectors at the national level in the same direction and rate for estimating the Rajasthan proportions. For the industrial sub-sectors' gross output and total input use proportions, the same data sources and methods were used as described above in section IV-A.

For supra-regional transactors and services, we adopt the national input use coefficients for the respective columns for Rajasthan state.

The input use coefficient matrix for Rajasthan based on the non-survey method was obtained by consolidating the above estimates for the respective coefficients. After post multiplying the input use coefficient matrix by the make matrix for 1984-85 obtained from the Technical Note on 7th Plan, we get the input-output coefficient matrix for Rajasthan, which is presented below in Appendix Table 3. The corresponding transaction table for Rajasthan State for the year 1984-85 at current prices based on the non-survey method is presented in Appendix Table 4.

VI. Analysis of the Results

The two alternative methods of estimating the regional I/O matrices give two different sets of estimates of the coefficients. Since both are estimates, their comparison has to be made with respect to some well-defined common characteristic. As we have discussed in the beginning, the need for regional matrices is felt basically to capture the extent of regional variation in the technology. We should, therefore, examine the deviations of the regional matrices obtained by the two alternative methods from the national matrix. The summary of the results in terms of frequency distributions

of deviations from the national input-use matrix of the estimated regional matrix by the survey and the non-survey methods are presented below in a tabular form :

Frequency Distribution of the Deviations of
Rajasthan Input-Use Coefficients from the
National Coefficients, 1984-85

Frequency Range	Frequency of Differences Between Survey Based Non-Survey - National Based - National
-0.15 or less	16 8
-0.149999 to -0.1	8 4
-0.099999 to -0.05	25 11
-0.049999 to -0.01	130 65
-0.009999 to -0.001	257 166
-0.000999 to -0.0001	106 196
-0.000099 to -0.00001	15 30
-0.000009 to +0.000009	1480 1363
0.00001 to 0.000099	74 177
0.0001 to 0.000999	178 336
0.001 to 0.009999	117 111
0.01 to 0.049999	58 27
0.05 to 0.099999	17 4
0.1 to 0.149999	4 2
0.15 or more	15 0
Total	2500 2500

From these frequency distributions of the deviations of regional coefficients from the national coefficients, it is evident that the Rajasthan input use coefficients differ on the whole from the national ones. Although most of the coefficients of Rajasthan are not different from the national coefficients in the first three decimal places, about 3% of the total coefficients of Rajasthan differ from the national ones by 0.05 or more. In specific sectors or activities, therefore, there appears to be considerable regional differences in the technology as reflected by input use coefficients. The most interesting question in this regard is whether the non-survey based method of estimating regional I/O matrix performs as efficiently as the survey based method in capturing the regional variations in the coefficients. We may use the test of mean difference for this purpose on the distributions of differences of regional input use coefficients and national coefficients. When we consider all the observations (i.e. 2500 coefficient differences), the calculated t-value turns out to be only 0.2923 which is statistically insignificant. This implies that the average overall difference of the regional coefficient from the national coefficient remains statistically the same whether we use the survey based method or non-survey based method to estimate the regional coefficients. Thus, if the purpose is to capture the overall difference of the regional technology from the national technology, both the survey based and non-survey based methods of estimating the regional coefficients appear to perform almost equally.

If, however, our purpose is to look into the differences of regional technology from national technology in the sector-activity-specific context, we need to consider those ranges of differences which are more than 5 percentage points in absolute terms. If we apply the mean difference test only to these ranges of differences in the two methods, we get the calculated t-value of 2.7454 which is significant at 5% level of significance. This implies that on an average the differences in regional coefficients from national coefficients when exceed 0.05 in absolute terms, the two methods of estimating regional coefficients differ statistically significantly. Thus, if our interest is to capture sector-activity -specific differences in the regional technology, we have to make a conscious choice between the two alternative methods of estimating the regional coefficients. It is obvious at this stage that survey based method should be given priority over the non-survey based method if the estimates based on the former are available for any regional economy.
